Abstract:

The Specker-Blatter Theorem states that number of labeled graphs over n vertices satisfying an MSOL-definable property satisfies a linear modular recurrence relation for every modulus m.

We give a gentle survey of the statement, the proof and applications.

Congruences for infinitely many

combinatorial functions

- Let P be a graph property, and let

$$d_P(n) = |\{E \subseteq [n]^2 : ([n], E) \in P\}|$$

be the number of ways one can find an edge relation E on the set $\{1, \ldots, n\}$ to obtain a graph $G = ([n], E) \in P$.

- $d_P(n)$ is called the density function of P.

- If P is monotone (hereditary) it is called the speed of P.

C. Blatter and E. Specker study
algebraic properties of density functions already in **1980**.

Only in **1994**, E. Scheinerman and J. Zito initiate the
study growth rates of density functions for hereditary properties,
and relate thenm to structural properties of graphs $G \in P$.

Comes the Hungarian School....

The Scheinerman-Zito paper started a new line of research:

The original theorem

(C. Blatter and E. Specker 1980)

Let P be a property of structures $(A, R_i), i \in [k]$, where

(i) each R_i is a unary or binary relation,

(ii) P is definable using Monadic Second Order Logic $\mathbf{MSOL}$,

Let d_P the density function for P and d_P^m be the sequence

$$d_P^m(i) = d_P(i) \mod m.$$

Then $d_P^m(i) : i \in \mathbb{N}$ is ultimately periodic.

It was left open, whether

(i) the restriction in (i) to at most binary relations was necessary, and

(ii) the restriction in (ii) to $\mathbf{MSOL}$ among fragments of Second Order Logic $\mathbf{SOL}$ was necessary.

The density function for regular graphs

J.H. Redfield's Theorem, 1927

The class $\mathrm{REG_r}$ of simple regular graphs where every vertex has degree r is FOL-definable (for fixed r).

Counting the number of labeled regular graphs is treated completely in Chapter 7 of the book:
Harary, Frank, and Edgar M. Palmer. Graphical enumeration, 1973, reprinted by Elsevier, 2014.
where an explicit formula is given, essentially due to J.H. Redfield (1927) and rediscovered by R.C. Read (1959).

However, the formula is very complicated.

For cubic graphs, the function is explicitly given: $f_{\mathcal{R}_3}(2n+1) = 0$ and

$$f_{\mathcal{R}_3}(2n) = \frac{(2n)!}{6^n} \sum_{j,k} \frac{(-1)^j (6k-2j)! 6^j}{(3k-j)!(2k-j)!(n-k)!} 48^k \sum_i \frac{(-1)^i j!}{(j-2i)! i!}$$

Can you see that this is ultimately periodic mod 17?

Regular graphs of even degree

- Eulerian graphs are connected graphs of even degree.
- Graphs of even degree are not $\mathbf{MSOL}$-definable, neither are Eulerian graphs.

Let $\mathbf{CMSOL}$ be the logic obtained from $\mathbf{MSOL}$ by adding modular counting quantifiers:

$$C_{m,a}(x)\phi(x)$$

which say that the set elements satsifying $\phi(x)$ in a finite structure $\mathfrak{A}$ has size a modulo m.

Regular graphs of even degree, and Eulerian graphs are $\mathbf{CMSOL}$-definable.

What can we say about $d_{EULER}(n)$?

$d_{EULER}(n)$ is not a special case of the Blatter-Specker Theorem!

Two equal-sized cliques

Let EQ_2 the class of finite graphs which consist of the disjoint unions of two equal-sized cliques.

EQ_2 is not $\mathbf{CMSOL}$-definable, but it is $\mathbf{SOL}$-definable.

We look at its density function $d_{EQ_2}(n)$. We have

$$d_{EQ_2}(n) = \begin{cases} \frac{1}{2}\binom{2m}{m} & \text{for } n = 2m \\ 0 & \text{else} \end{cases}$$

The factor $\frac{1}{2}$ is there because we cannot distinguish the choice of the first clique from the choice of its complement.

Proposition: (Lucas, 1878)
For every n which is not a power of 2, we have $d_{EQ_2}(n) \equiv 0 \pmod 2$, and for every n which is a power of 2 we have $d_{EQ_2}(n) \equiv 1 \pmod 2$.

In particular, $d_{EQ_2}(n)$ is not ultimately periodic modulo 2.

A proof may be found as Exercise 5.61 in:
R. Graham, D. Knuth and O. Patashnik,
Concrete Mathematics, 2nd ed., Addison-Wesley 1994

E. Fischer's counter example

- From 2000 I started to lecture about the Specker-Blatter theorem.
- In 2002 Eldar Fischer, attending my lecture, found a counter example:

Theorem: There is a property of finite structures with one quaternary relation, which is even **FOL**-definable but violates the Blatter Specker Theorem.

Fischer, Eldar. "The SpeckerBlatter theorem does not hold for quaternary relations." Journal of Combinatorial Theory, Series A 103.1 (2003): 121-136.

Recent work

E. Specker was intrigued and excited by Fischer's example.

- Specker, E.
  "Modular Counting and Substitution of Structures."
  Combinatorics, Probability & Computing 14.1-2 (2005): 203.

E. Fischer, and later my PhD student T. Kotek and I
analyzed the proof of the Blatter-Specker Theorem:

submitted to the special issue of Fundamenta Informaticae
celebrating the centenary of Boris (Boaz) A. Trakhtenbrot

The Tutte polynomial

- The Tutte polynomial $T(G; X, Y)$ is defined as

$$T(G; X, Y) = \sum_{S \subset E(G)} (X-1)^{\kappa(E)-\kappa(S)} \cdot (Y-1)^{|S|-\kappa(S)}$$

  where $\kappa(S)$ is the number of connected components of the spanning subgraph $G[S] = (V, S)$.

- I. Gessel (1979), and independently I. Pak (1993), proved:

$$T(K_n; a, b) = \sum_{k=1}^{n} \binom{(n-1)}{(k-1)} \left(a + \sum_{i=1}^{k-1} b^i \right) T(K_{k-1}; 1, b) \cdot T(K_{n-k}; a, b)$$

What can we say about $T(K_n; a, b)$?

What can we say about $T(K_n; a, b)$ modulo μ?

Evaluations of $T(K_n; a, b)$

- $T(K_n; 2, 1)$ counts the number of forests on n vertices.
- $T(K_n; 1, 1)$ counts the number of trees on n vertices.
- $T(K_n; 1, 2)$ counts the number of connected graphs on n vertices.
- $C_n(b) = T(K_n; 1, b)$ has been analyzed by A. P. Mani and R.J. Stones (2016) mod p^k.

A.P. Mani and R.J. Stones,
The number of labeled connected graphs modulo prime powers,
SIAM. J. Discrete Math., 30.2 (2016), pp. 1046-1057

They then formulate a conjecture for $T(K_n; a, b)$.

The conjecture by A. P. Mani and R.J. Stones

SIAM J. Discrete Math., vol. 30.2 (2016), 1046-1057

Let $\phi(m)$ be the Euler totient function, which is defined as the number of integers $a \in [m]$ such that $\gcd(a, m) = 1$.

Let p be an odd prime and let k be a positive integer.

- If $n \geq p^k$, $a, b \in \mathbb{Z}$, and $b \neq 1 \mod p$, then

$$T(K_n; a, b) = \mod p \begin{cases} b^{\frac{\phi(p)}{2}-1} & \text{if } p \geq 3, n = p \text{ and } a = 1 \mod p \\ b^{\frac{\phi(p^k)}{2}} \cdot T(K_{n-\phi(p^k)}; a, b) & \text{otherwise} \end{cases}$$

- If $n \geq p^k$, $a, b \in \mathbb{Z}$, and $b = 1 \mod p$, then

$$T(K_n; a, b) = \mod p^k \begin{cases} (n+a-1)^{p^k} \cdot T(K_{n-p^k}; a, b) & n > p^k \\ (a-1)^{p^k-1} & n = p^k \end{cases}$$

Although, Mani and Stones cite our chapter on "Application of Logic to Combinatorial Sequences", they misquote and obviously did not read it properly, missing out on the Specker-Blatter Theorem.

Inspired by the conjectures of
Mani and Stones we show

Theorem: (T. Kotek and JAM)
For every $a, b, \mu \in \mathbb{N}^+$ with $a, b > 1$,
$\gcd(a-1, \mu) = 1$ and $\gcd(b-1, \mu) = 1$,
the sequence $T(K_n, a, b)$ is ultimately periodic modulo μ.

Theorem: (T. Kotek and JAM)
If P is a graph polynomial hypergraph-definable in
extended $\mathbf{MSOL}_{hyperg}$ without order,
then for every $\mu \in \mathbb{N}$ and every $a, b \in \mathbb{Z}$
the sequence $P(K_n, a, b)$ is ultimately periodic modulo μ.

Variations on Stirling numbers of the second kind, I

Let $a, m \in \mathbb{N}^+$ and $A \subseteq \mathbb{N}^+$.

- $S(n, a)$ counts the number of partitions of $[n]$ into a non-empty sets.
- $S(n, a)$ is ultimately periodic modulo m since (for fixed a) the generating function is rational:

$$\sum_{n=0}^{\infty} S(n, a)x^n = \frac{x^a}{(1-x)(1-2x)\cdots(1-ax)}.$$

- Let $S_A(n, a)$ count the number of partions of $[n]$ into a non-empty sets of cardinalities in A.
- $S_A(n, 1) = \begin{cases} 1 & n \in A \\ 0 & n \notin A \end{cases}$. Hence A is ultimately periodic iff $S_A(n, 1)$ is.

Variations on Stirling numbers of the second kind, II

Theorem: (JAM and V. Rakita)
For every fixed a, m the sequence $S_A(n, a)$ is ultimately periodic modulo m iff A is ultimately periodic.

I am confident, but not sure that there is an elementary direct proof of this with explicit description of the ultimate periodicity.

However, using the Specker-Blatter Theorem gives it **without computations**.

Computing $S(n,2)$ and $S(n,3)$

$S(n,2)$ can be computed by counting all pairs of non-empty subsets $A, B \subset [n]$ of size k_A, k_B each. We note that $k_B = n - k_A$ and $k_A = n - k_B$ are both counted. We conclude that

$$S(n,2) = 2^n - 2/2$$

But we can also count as follows

$$S(n,2) = \frac{1}{2}\sum_{j=1}^{n-1}\binom{n}{j} = \sum_{n>j\geq n-j>0}\binom{n}{j}$$

Similarly we get

$$S(n,3) = \sum_{n>k_1\geq k_2\geq n-(k_1+k_2)>0}\binom{n}{k_1}\binom{n-k_1}{k_2}$$

Using the usual recurrence relation for $S(n,k)$ we get

$$S(n,3) = \frac{1}{2}(3^{n-1} - 2^n + 1)$$

Checking for $n = 4$ we get with both methods $S(4,3) = 6$.

Computing $S_A(n,a)$

We put $\ell_0 = 0$, $\ell_1 = k_1$ and $\ell_{i+1} = \ell_i + k_{\ell+1}$ and compute:

$$S_A(n,a) = \sum_{k_1 \geq \ldots \geq k_a} \prod_{i=1}^{a} \binom{n-\ell_{i-1}}{k_i}$$

where $\sum_{i=1}^{a} k_i = n$ and $k_1, k_2, \ldots, k_a \in A$.

Using the fact that

$$\binom{n}{a}\binom{n-k}{j} = \binom{n}{j}\binom{n-j}{k}$$

we see that the product in the above equation is magenta independent of the order of the numbers $k_i \in A$. As we assume $k_1 \geq \ldots \geq k_a \in A$ we sum over all ways n can be written as a sum of a summands in A only once.

Simplifying the product we get that for every $m \in \mathbb{N}^+$

$$S_A(n,a) = n! \cdot \sum_{k_1 \geq \ldots \geq k_a \in A} \prod_{i=1}^{a} \frac{1}{k_i} = n! \cdot f(n)$$

for $f(n)$ not an integer, hence we cannot conclude that $n! \cdot f(n) \neq 0 \mod m$.

Example: $2^n = \sum_{j=0}^{n} \binom{n}{j} = \sum_{j=0}^{n} \frac{n!}{j!\cdot(n-j)!} = n! \cdot \sum_{j=0}^{n} \frac{1}{j!\cdot(n-j)!} \not\equiv 0 \mod 3$

Eldar Fischer

Tomer Kotek

- Fischer, Eldar, Tomer Kotek, and Johann A. Makowsky.
  "Application of logic to combinatorial sequences and their recurrence relations.",
  in: Model Theoretic Methods in Finite Combinatorics,
  volume 558 of Contemporary Mathematics, (2011): 1-42.

Separating Logic from Combinatorics

C. Blatter and E. Specker associate with a property P of relational structures a rank, the substitution rank, with values in $\mathbb{N} \cup \{\infty\}$.

The logic part of their theorem is the following:

Proposition: If P is $\mathbf{MSOL}$-definable this rank is finite.

We (EF and JAM) prove:

Proposition: If P is $\mathbf{CMSOL}$-definable this rank is finite.

The rest of their (CB and ES) proof is algebra-combinatorial.

Proposition: If P is a property of structures with all relations at most binay, and P has finite rank, then $d_P^m(n)$ is ultimately periodic for every $m \in \mathbb{N}$.

This now covers also the case of **Eulerian graphs** and **regular graphs of even degree**.

Refining the analysis of the CB-ES proof

- We also take into account the

  maximal degree of the structures in P.

- We generalize the Substitution rank of a property P using

  Hankel matrices.

Relations of bounded degree

Let $\mathcal{A} = \langle A, \bar{R} \rangle$ be a τ-structure.
We define a symmetric relation E_A on $\mathcal{A}$, and call $\langle A, E_A \rangle$ the Gaifman-graph of $\mathcal{A}$.

- Let $a, b \in A$. $(a, b) \in E_A$ iff there exists a relation $R \in \bar{R}$ and some $\bar{a} \in R$ such that both a and b appear in $\bar{a}$
(possibly with other members of A as well).

- For any element $a \in A$, the degree of a is the number of elements $b \neq a$ for which $(a, b) \in E_A$.

- We say that $\mathcal{A}$ is of bounded degree d
if every $a \in A$ has degree at most d.

- We say that $\mathcal{A}$ is connected
if its Gaifman-graph is connected.

- For a class of structures $\mathcal{P}$ we say it is of bounded degree d (resp. connected) iff all its structures are of bounded degree d (resp. connected).

The Specker-Blatter Theorem revisited, I

Theorem(E. Fischer and JAM, 2002)

Let $\mathcal{P}$ be a property of τ-structures, which is $\mathbf{CMSOL}$-definable.
Let $d_{\mathcal{P}}(n)$ be its density function.

- If $\mathcal{P}$ is of bounded degree d,
  the function $d_{\mathcal{P}}(n)$ satisfies a modular recurrence relation for every m.

- Furthermore, if additionally all the models in $\mathcal{P}$ are connected,
  the function $d_{\mathcal{P}}$ satisfies the trivial recurrence relations for every m.

We have no restrictions on τ

besides not allowing function symbols,

Hankel matrices for graph properties, I

- A k-graph of order n is a graph $G = (V(G), E(G), a_1, \ldots, a_k)$ with $V(G) = [n]$ together with k distinct vertices $a_1, \ldots, a_k$.

- Let $\square$ be a binary operation on k-graphs.

  $\square$ could be

  (i) $\sqcup$, the disjoint union of graphs (without labels),

  (ii) $\sqcup_k$, the k union of k-graphs formed by taking the disjoint union and then identifying corresponding distinct vertices.

  (iii) or the substition $S(G, H)$ of a 1-graph G for the distinct label a of the 1-graph H.

Hankel matrices for graph properties, II

- Let $G_i, i \in \mathbb{N}$ be an enumeration of all finite k-graphs.
- Let P be a graph property.
- We define the infinite $(0,1)$-matrix $\mathfrak{H}(P,\Box)$ with

$$\mathfrak{H}(P,\Box)_{i,j} = \begin{cases} 1 & G_i \Box G_j \in P \\ 0 & G_i \Box G_j \notin P \end{cases}$$

- We denote by $rk(P,\Box)$ the rank of $\mathfrak{H}(P,\Box)$ over the field $\mathbb{Z}^2$.

The matrix $\mathfrak{H}(P,\Box)$ is called the **Hankel matrix** of P and $\Box$ for k-graphs.

Unknowingly, C. Blatter and E. Specker use
a special case of Hankel matrices.

Hankel matrices (over a field $\mathcal{F}$)

Let $f : \mathcal{F} \to \mathcal{F}$ be a function over a field $\mathcal{F}$.

A finite or infinite matrix $H(f) = h_{i,j}$ is a Hankel matrix for f if $h_{i,j} = f(i+j)$.

Hankel matrices have many applications in:
numeric analysis, probability theory and combinatorics.

- Padé approximations
- Orthogonal polynomials
- Probability theory (theory of moments)
- Coding theory (BCH codes, Berlekamp-Massey algorithm)
- Combinatorial enumerations
  (Lattice paths, Young tableaux, matching theory)

Hankel matrices over words

Let Σ be a finite alphabet and $\mathcal{F}$ be a field and let $f : \Sigma^\star \to \mathcal{F}$ be a function on words.

A finite or infinite matrix $H(f) = h_{u,v}$ indexed over the words $u, v \in \Sigma^\star$ is a Hankel matrix for f if $h_{u,v} = f(u \circ v)$. Here $\circ$ denotes concatenation.

Hankel matrices over words have applications in

- Formal language theory and stochastic automata,
  J. Carlyle and A. Paz 1971
- Learning theory (exact learning of queries).
  A.Beimel, F. Bergadano, N. Bshouty, E. Kushilevitz, S. Varricchio 1998
  J. Oncina 2008
- Definability of picture languages.
  O. Matz 1998, and D. Giammarresi and A. Restivo 2008

Hankel matrices for graphs

If we want to define Hankel matrices for (labeled) graphs,

what plays the role of concatenation?

- Disjoint union
  Used by Freedman, Lovász and Schrijver, 2007, for
  characterizing multiplicative graph parameters over the real numbers

- k-unions (connections, connection matrices)
  Used by Freedman, Lovász, Schrijver and Szegedy, 2007ff, for
  characterizing various forms and partition functions.

- Joins, cartesian products, generalized sum-like operations
  used by Godlin, Kotek and JAM (2008) to prove non-definability.

The $\Box$-rank of a property P

Given

- a binary operation $\Box$ between structures $\mathfrak{A}(A, \bar{R}, \bar{F}, \bar{c})$ with relations $\bar{R}$, functions $\bar{F}$ and constants $\bar{c}$), and no restrictions on their number of arguments, and

- a property P of such structures

we say that P has $\Box$-rank $r(P, \Box) \in \mathbb{N} \cup \{\infty\}$ if $r(P, \Box) = rk(P, \Box)$ is the rank of the Hankel matrix $\mathfrak{H}(P, \Box)$ over the field $\mathbb{Z}^2$.

$\mathcal{L}$-smooth operations.

Let $\mathcal{L}$ be a logic with a well defined quantifier rank.

Here $\mathcal{L}$ is one of $\mathbf{FOL}, \mathbf{MSOL}, \mathbf{CMSOL}$.

We say that two graphs G, H are $(\mathcal{L}, q)$-equivalent,
and write $G \sim^q_{\mathcal{L}} H$, if G and H satisfy the same $\mathcal{L}$-sentences of quantifier rank q.

We say that $\Box$ is $\mathcal{L}$-smooth, if whenever we have

$$G_i \sim^q_{\mathcal{L}} H_i, i = 0, 1$$

then

$$G_0 \Box G_1 \sim^q_{\mathcal{L}} H_0 \Box H_1$$

This definition can be adapted to k-graphs and also to structures with k-ary operations for $k \geq 1$.

Proving that an operation $\Box$ is $\mathcal{L}$-smooth

Proving that an operation $\Box$ is $\mathcal{L}$-smooth may be difficult.

For **FOL**, $\mathbf{MSOL}$ and $\mathbf{CMSOL}$ this can be achieved using

Ehrenfeucht-Fraïssé games also know as pebble games.

The case for $\mathbf{MSOL}$ was first proved by Hans Läuchli in 1966.

Anther way of establishing smoothness is via generalizations of the Feferman-Vaught theorem.

Makowsky, Johann A. "Algorithmic uses of the FefermanVaught theorem." Annals of Pure and Applied Logic 126.1-3 (2004): 159-213.

In this talk we need two cases:
$\Box = \sqcup$, the disjoint union, and $\Box = Subst$, the substution of pointed graphs.

Theorem:(EF and JAM) Both $\sqcup$ and $Subst$ are $\mathbf{CMSOL}$-smooth.

The Finite Rank Theorem

Theorem (Godlin, Kotek, Makowsky 2008):

Let f be a numeric graph parameter or graph polynomial for τ-structures definable in $\mathcal{L}$ and taking values in an integral domain $\mathcal{R}$.

Let $\Box$ be an $\mathcal{L}$-smooth operation.

Then the Hankel matrix $\mathfrak{H}(f, \Box)$ has finite rank over $\mathcal{R}$.

****

The **Proof** uses a Feferman-Vaught-type theorem for graph polynomials, due to B. Courcelle, J.A.M. and U. Rotics, 2000.

C. Blatter and E. Specker prove it for $Subst$ and $\mathbf{MSOL}$.

L. Lovasz proves it for patition functions.

It has many applications in graph theory.

Bounded $\sqcup$-rank and bounded degree

Theorem(EF and JAM, 2002)

Let P be a property of structures over some fixed vocabulary.
If P has finite $\sqcup$-rank and
all its members of are bounded degree d. Then

- $d_P^m(n)$ is ultimately periodic for every m.
- Furthermore, if additionally all the models in P are connected, $d_P^m(n) = 0$ for all m and n.

Example $d_{EQ_2}(n)$ shows that bounded degree cannot be dropped, even for $\sqcup$-rank 2 (and connected structures).

For structures of unbounded degree one needs a stronger assumption, the finiteness of the $Subst$-rank.

$\sqcup$-rank of $\mathcal{P}$ and Gessel-classes

- A class of structures P is a Gessel class if for every $\mathfrak{A}$ and $\mathfrak{B}$, $\mathfrak{A} \sqcup \mathfrak{B} \in \mathcal{P}$ iff both $\mathfrak{A} \in \mathcal{P}$ and $\mathfrak{B} \in \mathcal{P}$.
- The class of forests is a Gessel class.
- If P is hereditary and closed under disjoint unions, it is a Gessel class.
- Every Gessel class has $\sqcup$-rank at most 2.
- If $\mathcal{P}$ is a class of connected graphs, $\mathcal{P}$ has $\sqcup$-rank at most 2, but is not a Gessel class.
- If $\mathcal{P}_1$ and $\mathcal{P}_2$ have finite $\sqcup$-rank, so do $\mathcal{P}_1 \cup \mathcal{P}_2$, $\mathcal{P}_1 \cap \mathcal{P}_2$, and the complement $\bar{\mathcal{P}}_1$.

Many classes of finite $\sqcup$-rank and $Subst$-rank.

There are only countably many classes of structures definable by $\mathbf{CMSOL}$-formulas.

How many classes are there of finite $\sqcup$-rank?

Proposition:(After an idea of Specker, 2002)

(i) There are continuum many Gessel classes.

(ii) There are continuum many properties of structures with $\sqcup$-rank 2.

(iii) There are continuum many properties of structures with finite $Subst$-rank.

Relation between $\sqcup$-rank and $Subst$-rank

We denote by $G \bowtie H$ the join of G and H.

Proposition: Let P be a graph property. We have

(i) $rk(P, \sqcup) \leq rk(P, Subst)$ and $rk(P, \bowtie) \leq rk(P, Subst)$.

(ii) The class HAM of Hamiltonian graphs is connected,
hence has $\sqcup$-rank 2,
However, HAM has infinite $\bowtie$-rank, hence also infinite $Subst$-rank.

Problem: What can we say about $d^m_{HAM}(n)$?

The widely overlooked paper: its merits

- It initiates a systematic study of
  congruence relations for combinatorial counting functions.
  Before, and still now, mostly special cases are studied.

- It anticipates the use of
  the rank of Hankel matrices in combinatorics
  In the recent work of L. Lovász and his many collaborators on
  graph limits and **partition functions**
  this plays a central role.

- It formulates for the first time a
  meta-theorem connecting definability in $\mathbf{MSOL}$ with combinatorics.
  The Büchi-Elgot-Trakhtenbrot Theorem characterizes
  regular languages using $\mathbf{MSOL}$.
  Bruno Courcelle and his collaborators use $\mathbf{MSOL}$-definability to show
  that $\mathbf{NP}$-hard problems are in $\mathbf{P}$ for graphs properties
  of **bounded tree- and clique-width**.

The widely overlooked paper: Our improvements

- Eldar Fischer gave a counter example using a quaternary relation.
- Analyzing the counter example we noticed the role of bounded degree structures and the role of the $\sqcup$-rank.
- Proving an earlier version of the Finite Rank Theorem for $\mathbf{CMSOL}$ we extended the Specker-Blatter Theorem to include Eulerian graphs (and many other cases).

Thank you for your attention
